ALFALFA AS A GRAZING CROP: PROGRESS CONTINUES

Garry Lacefield

This makes the third consecutive year that I have talked about "Alfalfa as a Grazing Crop." At our XIII Kentucky Alfalfa, I, along with five other speakers, discussed several aspects of grazing alfalfa and all agreed that the concept had tremendous potential.

This past year I reviewed some of the discussion of our XIII Conference and shared some of the activities going on in research and educational programs throughout the region. In addition, I announced the date for a National Alfalfa Grazing Conference to be held in Nashville, Tennessee. The Conference was held July 29 and was a big success. Over three hundred people from twenty-six states and three foreign countries attended. In addition to leading scientists speaking on many aspects of grazing, a real highlight of the Conference was presentations by four producers. The producers included: Dave Forrey, dairyman from Indiana; Dave Mercer, dairyman from Tennessee; JoAnn Bollmann, beef producer from Illinois; and our own Ken Johnson, beef producer, Monroe County, Kentucky. Proceedings from the Conference are available from the Certified Alfalfa Seed Council, Inc., P. O. Box 1017, Davis, CA 95617-1017 at a cost of $15.00. The Conference was such a success, the interest and potential is such that a second National Alfalfa Grazing Conference is being planned.

Now, let's review some of the aspects of alfalfa that makes it such a special crop and a crop that has a lot of potential as a grazing crop.

Alfalfa is the most important forage legume grown in the United States. Grown over a wide range of soil and climatic conditions it has the highest yield potential and feeding value of all perennial forage legumes. This versatile crop can be used for hay, pasture, silage, green-chop, pellets, cubes and soil improvement. Because of its many merits, especially yield, quality and versatility, it can be used successfully in many animal feeding programs.

Grazing alfalfa has not been practiced to any great extent in the U.S., but has been done extensively in other countries. Research and producer experience has shown excellent gains per animal and per acre without shortening the alfalfa stand's life expectancy.

Advantages of Alfalfa as a Grazing Crop

(1) Versatile Use — Alfalfa can be ideal on farms where it can be used for hay, silage, or grazing. Virginia workers studied systems of grazing alfalfa based

1Extension Forage Specialist, University of Kentucky Research & Education Center, Princeton.
on need and environmental conditions. Systems of grazing the early spring growth provided quality feed and delayed the first hay harvest until more favorable weather for curing. Other systems provide grazing during midsummer when cool-season grasses are often less productive. Comparing the systems shows that total season yield is not reduced by any graze-hay systems.

(2) With proper grazing management, alfalfa’s high yield potential can be converted to high levels of animal production per acre. Liveweight gains per acre are quite high for grazing beef cattle, with total season gains of 500 to over 800 lb/acre in research trials and on-farm demonstrations.

(3) Alfalfa’s quality for grazing is excellent, resulting in total season average daily gains over 2 lb/day in grazing trials and demonstrations.

(4) Alfalfa’s deep root system makes it more drought tolerant than our other cool-season legumes and grasses. Although alfalfa does not make maximum growth during summer droughts, it usually provides good summer pastures. During extreme drought this aspect becomes even more important since cool-season grasses become dormant.

(5) **Extended Use of Stand** — For old alfalfa fields that have been used for hay but where some of the stand has been lost or become weedy, grazing can extend the stand’s useful life a year or more. Grazing may also rejuvenate some stands by reducing grass and weed competition. **Research results** — When alfalfa stands decline to less than 3 plants/sq ft, optimum hay yields usually cannot be achieved. Excellent beef gains have been made on alfalfa stands with as few as 1 plant/sq ft although productivity per acre suffers.

(6) **Reduced Machinery Cost** — Over 40% of the cost of producing alfalfa hay is machinery and equipment. In a total grazing system, this cost can be eliminated or certainly minimized.

**Grazing Alfalfa—Concerns**

(1) The most frequent concern of producers considering grazing alfalfa is bloat, but it can be minimized with precautions. Producers may lose more money from the fear of bloat than from bloat itself if it keeps them from efficiently using the alfalfa pasture.

(2) **Additional Fencing** — Alfalfa must be grazed on a rotational basis. Doing so requires that fields be subdivided so that cattle are restricted to one area for a time, then moved to another area. This system gives the grazed area time to regrow before grazing again. Fencing does not have to be elaborate or
complex. Simple low-cost electric fences that restrain animals to a given area are adequate. Access to water and minerals is also important.

(3) **Greater Management and Labor Inputs** — Although some consider this category to be a disadvantage, advocates of controlled grazing do not always agree. Once the necessary fencing is in place, time studies have shown that the amount of additional labor required for rotational grazing is quite small compared to harvesting hay. In addition, regularly moving cattle to new pastures lets the producer observe them more closely and therefore permits greater cattle-pasture management efficiency.

(4) **Stand Decline** — If alfalfa plants are not grazed properly, stands decline. Grazing animals may damage alfalfa crown during wet and muddy conditions. In addition, damage to new crown shoots can occur when cattle are left on an individual paddock after new shoots develop. These disadvantages can be minimized with the following practices:

- To avoid damage to stands, use a "sacrifice paddock" next to the alfalfa where you can put cattle during wet and muddy conditions.

- Do not let cattle graze an individual paddock for over 10 to 12 days to minimize damage to newly developed shoots. Exceptions to the 12-day rule include the first grazing in spring and times when alfalfa is dormant (during drought and after freeze down).

**Requirements for Grazing Alfalfa**

**Establishing the Stand**

Requirements for establishing an alfalfa stand for grazing are similar for hay. Advances in variety development has shown that some varieties have greater tolerance to grazing than traditional hay-type varieties. A thick, healthy and productive stand has the greatest potential for animal performance and production per acre. Although pure stands can be grazed successfully, alfalfa-grass mixtures have advantages in grazing situations. Alfalfa-grass pastures may minimize bloat, and reduce the amount of hoof damage and soil erosion.

Recommendations for grazing alfalfa that have been used for many years reflect and approximate hay harvest: i.e. graze rotationally, provide for a rest or recovery period, then graze again. For example, if a crop of hay would have been taken every 35 days, then a rotation schedule would be set to complete one cycle in that time. Consider the number of paddocks, stocking rate, grazing time, recovery period, ease of cattle movement, water, salt and minerals.
Rotations (graзе-rest)

Research has clearly shown that rotational grazing is better than continuous grazing for yield, quality and stand persistence. General recommendations are to graze a paddock for one week or less and allow 4 to 6 weeks for plants to recover before grazing again. Considerable flexibility exists in the grazing time, but plants should not be grazed for more than 10 to 12 days. If they are grazed that long, new shoots developing from crown buds will likely be damaged. Therefore, stocking density should be heavy enough to remove growth in 10 to 12 days or less. With more intensive systems and high stocking density, growth can be removed in 1 or 2 days. Intensive systems require many paddocks and frequent cattle movement. Time required before a paddock can be grazed again depends on growing conditions. Under good conditions with rapid growth, the rest period is 4 weeks or less. During less favorable growing conditions, 4-6 weeks may be needed.

Special considerations should be given when grazing new stands. Plants need to become well established before grazing to avoid damage. The first crop could be taken for hay or silage and begin grazing on the next growth to minimize damage to new seedlings.

Alfalfa should be grazed closely enough so that regrowth occurs from the crown. This situation not only ensures good utilization but also helps control weeds. An exception occurs during the fall grazing period. General recommendations have been to make the season's last cutting by mid-September, because growth from mid-September until freeze-down ensures root reserves for overwintering and regrowth the following spring. However, research has shown that alfalfa plants can be grazed during this period if they are not grazed short. To accomplish this rotate animals more frequently or reduce stocking rates. Grazing during September 15 to November 1 should ensure that at least 8 inches of growth remains when animals are moved. Quality and animal performance can be quite high, since animals are only eating high quality plant tops.

Number of Paddocks

Dividing the alfalfa field into smaller areas (paddocks) is necessary for rotational grazing. You need enough paddocks to permit proper grazing management but few enough to meet individual management resources. Consider starting with a minimum of 5 individual paddocks. Having this number lets you rotating animals to a new paddock each week with a 4-week recovery. During peak growth, you may need to further divide one or more paddocks to permit longer recovery periods.

Be sure to consider placement of gates and lanes, access to water, ease of cattle movement, and the slope and lay of the land when designing the fencing and paddock system. Also provide a sacrifice paddock.
Stocking Rate

Stocking rate is defined as the number of animals grazing over an area during the grazing season. Stocking density is defined as the number of animals grazing an area at a particular time. Past productivity influences how many animals a given area will support (carrying capacity).

Alfalfa’s high yield potential and high quality furnish enough feed for a high stocking rate. On good, productive stands, stocking rates of 3 to 5 animals per acre are generally suggested. Adjustments can be made based on the stand’s productivity, animal needs, experience in grazing management and risk levels that a producer is willing to assume.

Bloat Precautions

No management practice can ensure that bloat will not occur. However, its likelihood can be decreased so much that grazing alfalfa can become common. The following suggestions can reduce the risk of cattle bloat:

- Grow grass with alfalfa.
- Feed bloat-preventing compounds.
- Do not turn hungry cattle into an alfalfa field, especially when plants are wet from dew.
- Do not graze immature alfalfa or alfalfa-grass.
- Provide salt and minerals.
- Observe cattle closely when turning in for the first time.
- Observe cattle closely during cool, cloudy, rainy weather for signs of bloat.

Conclusion

Alfalfa is a high yielding, high quality, versatile forage legume well adapted throughout the U.S. Gains per animal and per acre can be excellent with acceptable stand persistence when present technology is used.
