### Introduction

Goat farming is very popular in the Philippines as it is considered by many to be a viable rural enterprise. Despite this, the goat industry is faced with many challenges, including problems relating to high pre-weaning mortality, poor nutrition and lack of strategic approaches to accelerate genetic improvement. The long term rate of increase of goat numbers is only 0.97% per annum, due to high offtake rates and low productivity. Thus, the Philippine goat population is only expected to reach 4.27 million by 2020 (compared with the target of 6.2 million) given the 3.88 million population in 2010 (Alo 2012). Interventions are needed to accelerate growth of the goat population.

Goats are typically fed on locally available resources which are characterised by low quality and highly variable availability. These characteristics can be overcome through processing techniques such as sun drying and pelleting to ensure year round feed supply. Pelleting offers particular advantages. Feeding animals with pellets provides better feed efficiency, greater starch digestibility, less feed waste, non-selective feeding, better handling and storage, and increased income due to more efficient feeding and higher productivity. While pellets are available for swine, poultry and buffalo in the Philippine market, pellets for goats are not currently available. The aim of this study was to develop pelletized forage-based rations for goats and evaluate them for their technical and financial viability.

### Methods

Leaves of the tree legume *Leucaena leucocephala* and Napier grass (*Pennisetum purpureum*) were harvested at about 35-days of age, shredded and sun dried for 3-4 days to attain 80-85% DM. These were ground to pass through 1 mm screen mesh using a hammer mill to produce leaf meals. The compositions of the experimental rations are shown in Table 1.

The two rations (PRG and PRL) were mixed and moistened to attain desired binding effects. These were pelleted using a machine designed and fabricated for this purpose. The pellets are 20-25 mm in length and 8 mm in diameter.

To evaluate PRG, a total of 16 Anglo-Nubian crosses with mean body weight (BW) of 12.46 kg were used in a 120 day-feeding trial. The animals were kept in individual pens and divided into two groups; 6 animals in the Control 1 group (silage +120 g concentrate) and 10 animals in the PRG. In the middle of the feeding trial, three animals were randomly selected from each group to determine digestibility of the PRG. Voluntary DM intake and fecal output for 7 days were collected.

To evaluate feeding value of PRL, a 105-day feeding trial was conducted using 12 multiparous goats (6 Anglo-Nubian crosses and 6 Boer crosses with mean body weight (BW) of 32.65 kg). For each breed type, 3 does were fed PRL + fresh Napier while 3 does were fed with Control 2 diet, forage + 250 g concentrate mix.

About 10% representative samples of feed, orts, and feces were collected, pooled and subjected to DM, and crude protein (Kjeldahl method) analysis following the AOAC (1984) procedure. Neutral Detergent Fiber was analyzed following Goering and Van Soest (1970) method.

Feed intake, BW, milk yield and nutrient digestibility were subjected to ANOVA using the General Linear Model
Table 2. DM intake, final wt and ADG and feed conversion efficiency of upgraded goats fed with Control and PRG. SEM = Standard Error of Mean; ns $P > 0.05$; * $P < 0.05$; ** $P < 0.01$.
