#### INTRODUCTION

As part of its highway safety improvement program, the Kentucky Transportation Cabinet utilizes the cost-optimization procedure of dynamic programming to rank highway safety improvements. The accuracy of the improvement costs and benefits (in the form of accident reductions) determines the effectiveness of this program. The procedure presently assumes a 100-percent reduction in accidents for any given safety improvement, but this generally does not occur in reality. The objective of this study is to develop a listing of factors that may be used to reasonably predict the reduction (or increase) in accidents expected upon implementation of a given safety improvement.

#### PROCEDURE

A review of literature pertaining to past and current studies related to benefits associated with safety improvements was conducted. Information from those sources was compiled to form a list of accident reduction factors for various highway safety improvements.

A survey of states was performed to determine what is being used currently by individual states. A letter was sent to all states to obtain information concerning accident reduction estimates used to rank highway safety improvements and the basis for those percentages (Appendix). The states were asked whether the percent reductions in accidents, if used, were based on before-and-after analysis related to implementation of the improvement, a review of relevant literature, or engineering judgment.

A before-and-after accident analysis of safety improvement projects in Kentucky was performed and a list of reduction factors was compiled for those safety improvements. Accident data for one or two years before implementation of the improvement and one or two years after implementation were obtained from the Accident Surveillance Section of the Division of Traffic. Average annual accidents before and after

implementation of safety improvements were compared to obtain the estimated percent reduction in all accidents related to implementation.

#### RESULTS

An attempt was made to compile a comprehensive list of all types of safety improvements from current literature and from other states. Although some safety improvements may have been excluded from the literature sources or returned survey responses, a large number of safety improvements and associated accident reduction factors was collected. Those safety improvements were grouped into the general categories listed in Table 1. Subsequent tables were based on all or part of those categories. All categories having characteristics in common, such as signs, were placed in the same category. Subdivisions by type of improvement within each category were made to provide clarity and organization. For example, the category "Signs" was subdivided by type of sign: Warning Signs, Regulatory Signs, Guidance Signs, Other.

### REVIEW OF LITERATURE

From the review of literature pertaining to past and present studies, 42 sources relating to accident reductions from highway safety improvements were obtained and are listed in the "References" section of this report. The majority of the sources described the effects of highway safety improvements in terms of percentage reductions in accidents. These are listed in Table 2. The remaining references related highway safety improvements to percentage reductions in accident rates and are listed in Table 3.

Some of the references listed reductions in accidents or accident rates by severity of accident -- fatal, injury, fatal and injury, and property damage only -- as well as reductions in total accidents or accident rates for a given safety improvement. Others listed only a total reduction in all accidents or rates for a given safety

improvement. Reductions for specific types of accidents such as wet pavement or nighttime accidents were listed by some of the references. Reductions in accidents or accident rates for some types of safety improvements varied widely among sources. For example, in the safety improvement category for signals in Table 2, the percentage reduction in all accidents corresponding to new signal installation ranged from 10 to 80 percent.

The source of the information given in Tables 2 and 3 is identified by the reference number as given in the listing of references. Some references were based upon findings of several previous studies and contained more than one list of reduction factors. Additional lists of reduction factors by the same reference are denoted by a lower case letter. For example, Reference 6, a 1966 report by Roy Jorgensen & Associates, contains three separate lists of accident reduction factors: a summary of before-and-after-results from a previous study, a list of forecasted reductions from the same study, and a list of reduction factors based on the Jorgensen study itself. These three lists are designated in Table 2 as References 6, 6a, and 6b, respectively.

#### SURVEY OF STATES

Table 4 summarizes the origin of reduction factors obtained from the survey of states. At the time of the survey, 22 states replied they did not use reduction factors in ranking highway safety improvements. Eleven states reported they developed their own factors through before—and—after studies, review of literature, engineering judgment, or a combination of the three. Twelve states adopted factors either from current literature or factors developed by other states. Five states —Kansas, New Jersey, New York, Texas, and Utah — used a combination of adopted factors and factors developed from their own studies. The expected percentage reductions in accidents for highway safety improvements according to reduction factors used by states are given in

Table 5, while percentage reductions in accident rates corresponding to highway safety improvements expected by states are given in Table 6.

The reduction factors listed in Tables 5 and 6 were either developed by the states listed or have been adopted from other sources. The source shown in these tables is either the state (noted by the state abbreviation) or the literature source from which the state adopted its factors (as noted in Table 4). Review of Tables 4, 5, and 6 reveals that Minnesota has developed its own reduction factors, but those factors are not listed in Table 5 or Table 6. Minnesota does not have a set of statewide reduction factors. Instead, individual highway districts are responsible for developing their own reduction factors. Two districts listed accident reduction factors for highway safety improvements. Those factors were given by type of accident (e.g. rear end, angle, head-on, right turn, etc.) and were incompatible with factors submitted by other states. Thus, they were not included in the tables.

### BEFORE-AND-AFTER ANALYSIS IN KENTUCKY

A before-and-after accident analysis of highway safety improvements in Kentucky was performed. Accident data were obtained for one-year or two-year periods before and after implementation of safety improvements. Average annual accidents before and after implementation were compared to determine the percentage reductions in total accidents for various types of safety improvements. Those results are given in Table 7.

#### CONCLUSION

Through a review of current literature and a survey of states, it was concluded that there is no commonly accepted list of factors that may be used to predict the percentage reduction in accidents corresponding to implementation of different types of highway safety improvements. Some states utilized developed or adopted factors for the

purpose of ranking safety improvements, while others preferred alternative methods. Nearly all states expressed an interest in such a set of factors.

#### DEVELOPMENT OF REDUCTION FACTORS

It was the objective of this study to derive a comprehensive list of accident reduction factors for the purpose of optimizing the priority ranking procedure of highway safety improvements in Kentucky. The development of a list of these reduction factors was based mainly on the review of literature and survey of states, with limited input from the before-and-after accident analysis in Kentucky.

Table 8 lists a set of recommended accident reduction factors for highway safety improvements. Some of those factors are based on before-and-after studies, others are based solely on engineering judgment, and some entail a combination of both. While many of these factors are judgmental, a step has been made toward developing a set of commonly accepted accident reduction factors. It is hopeful that this list will be continually improved and upgraded through before-and-after accident analyses so that in the future a reliable prediction of accident reductions associated with highway safety improvements may be utilized by all agencies.

### **IMPLEMENTATION**

The Division of Traffic of the Kentucky Transportation Cabinet uses a dynamic programming procedure as a means to priority rank safety improvements. To use this program, the user must provide certain vital information that includes expected reductions in accidents for each safety improvement. The accident reduction factors developed in this report (given in Table 8) can be used to provide that information.

## KENTUCKY TRANSPORTATION RESEARCH PROGRAM

UNIVERSITY OF KENTUCKY

College of Engineering
Transportation Research Building
533 South Limestone
Lexington, Kentucky 40506-0043
Telephone: 606-257-4513

March 1984

Dear

The Kentucky Department of Highways utilizes a cost-optimization procedure (called dynamic programming) to priority rank improvements in its highway safety improvement program. The effectiveness of this program is greatly dependent on the accuracy of the improvement costs and benefits (accident reductions) input into the computer program.

The University of Kentucky Transportation Research Program is performing a study for the Kentucky DOH with the objective of developing a state-of-the-art listing of accident reduction percentages or factors associated with various types of safety improvements. While it is difficult to assign accurate accident reduction factors for specific safety improvements, our objective is to develop a listing which can be used to reasonably predict the consequences of implementing a given safety improvement.

One phase of this study involves a survey of states to determine what is currently being used across the country. We would appreciate any information your office could provide concerning the accident reduction estimates your state used to rank improvements proposed as part of your safety improvement program. We also wish to know the basis for these percentages, that is, whether they are based on studies conducted before and after the installation of safety improvements, a review of relevant literature, or engineering judgment. We will provide you with a summary of the findings of our survey if you so indicate. We appreciate your assistance.

Sincerely,

Kenneth R. Agent, P.E. Research Engineer
