The Long-Term Decline in Kentucky’s General Fund Buoyancy
By Michael Childress (michael.childress@uky.edu) & William Hoyt (whoyt@uky.edu)

Kentucky’s recurring budgetary problems are due, in part, to the long-term decline in general fund revenue buoyancy—a measure of whether revenue is keeping pace with the economy.1 There are several economic, demographic, and political factors contributing to the gradual reduction in buoyancy.2 Given the systemic nature of these changes, the long-term decline in general fund revenue buoyancy will likely continue in the absence of tax reform. Here, we do not assess whether government spending is too high or too low, or if the size of government is too big or too small. If policymakers desire government spending to remain approximately proportional to the size of the economy, then general fund buoyancy determines whether sufficient revenue is available to do so without frequent increases in tax rates. This analysis illustrates the long-term decline of Kentucky’s general fund buoyancy, compares it to other states, and discusses some of the causes.

While year-to-year volatility is typical, over the long term revenue should change at approximately the same rate as the economy if the demand for government services and activities is more or less proportional to personal income. A buoyancy of 1.0 indicates that revenue growth is keeping pace with economic growth, while buoyancy less than 1.0 shows revenue is growing slower than the economy. The averages back to 1970 and 1985 are 1.09 and 1.07 respectively, but the averages back to 1995 and 2000 are lower at 0.84 and 0.76 respectively (see Figure 1).3 The 41-year trend illustrates the downward slope of buoyancy. It is also worth noting that a more buoyant revenue system means that with downturns in the economy contractions in revenue are larger. Thus buoyancy and stability may, at times, be two conflicting goals for a revenue system.

Revenue growth rates are affected by both changes in the revenue base and tax rates. Many states’ revenue growth rates are determined by their income generator—personal income in Kentucky’s case. Personal income flows into the state through a series of paths: wages, salaries, fees, professional earnings, and so on. These earnings are then subject to income taxation at both the federal and state level. The CAGR of personal income from 1979 to 1999 is 3.7%; from 2000 to 2010 it is 2.5%. The annual growth of personal income from 2000 to 2010 is 3.4%, which is lower than both the CAGRs. The buoyancy of personal income in Kentucky is typical, over the long term revenue should change at approximately the same rate as personal income. However, the average buoyancy of personal income in Kentucky is lower than the national average of 3.6%.

systems have failed to keep pace with overall economic growth during the past decade due to one or both of these factors. Using the ratio between the compound annual growth rates (CAGR) of the general fund and personal income, we compare Kentucky to the U.S. and surrounding states during two time periods—1979 to 1999 and 2000 to 2010. Just like the average buoyancy, a ratio of 1.0 indicates that the general fund is growing at the same rate as the economy. As shown in Table 1, Kentucky’s CAGR ratio is 1.08 during the earlier period. Tennessee, with a CAGR ratio of 0.68, is the only surrounding state with a CAGR ratio significantly below 1.0. However, in the more recent era, from 2000 to 2010, four states are well below 1.0—Illinois (0.29), Kentucky (0.70), Missouri (-0.18), and Virginia (0.55).

The decline in buoyancy will likely continue in the absence of fundamental tax reform. A multitude of systemic factors affect these sources of revenue, including the gradual shift in personal income away from taxable sources (e.g., wages, salaries, and proprietors’ income) and toward mostly nontaxable sources (e.g., some transfer payments and nontaxable employee benefits); the transition from a goods-producing economy that is taxed to a service-producing economy that is largely untaxed; the rise of “mail order” or remote retail sales, which includes Internet and catalog purchases; an aging population whose spending patterns generate less revenue compared to younger cohorts; and the prevalence of tax exemptions. While not the only factor causing Kentucky’s recurring budgetary problems, fixing the decline in general fund buoyancy will go a long way toward solving Kentucky’s structural deficit.

A multitude of factors are affecting the decline in Kentucky’s general fund buoyancy.

Notes

1General fund buoyancy and elasticity are related concepts. Both are defined as the annual percentage change in general fund revenue divided by the annual percentage change in personal income. However, while actual general fund and personal income numbers are used to calculate buoyancy, adjustments are made when calculating elasticity to reflect any changes to the tax code that affect rates or the base.

3The data are from the Kentucky OSBD, Kentucky Revenue Cabinet and the U.S. Bureau of Economic Analysis.

4The data used to calculate the compound annual growth rate for the general fund are from “The Fiscal Survey of States,” National Association of State Budget Officers, Fall, various years, available at <http://www.nasbo.org>.

6We exclude FY91 because there were significant changes made to the tax code in FY90 that skew the data for FY91.
