Comparison of Weed Management Strategies with Roundup Ready® Corn.

J. A. Ferrell and W. W. Witt

Introduction
Corn weed management during the past several years in Kentucky has centered around two herbicide families, the chloroacetamides (Dual, Frontier, Harness, Micro-Tech, Surpass) and the s-triazines (AAtrix, Bladex, Princep). These products have been used widely because they offer acceptable, full season control of many common warm season annual weeds at a reasonable price. This combination has been so popular that several mixtures that contain these types of herbicides (Bicep II, Bullet, Guardsman, Harness Xtra, Surpass 100, FulTime) are used commonly used in Kentucky. The key to this efficacious and economic program is atrazine because it controls most annual broadleaf species that exist in Kentucky corn production with minimal economic investment.

In addition to a good foundation soil-applied herbicide program for controlling annual weeds, a postemergence application of nicosulfuron (Accent) is often needed to help manage johnsongrass (Sorghum halepense). Including nicosulfuron as a part of a weed control program increases costs and may increase risk of corn injury due to antagonism with certain insecticides or untimely applications.

Monsanto released Roundup Ready® corn, which is a transgenic crop that is tolerant to glyphosate, in the spring of 1998. Glyphosate is the active ingredient in several products including Roundup Ultra and has long been used as a non-selective burndown herbicide for no-till production of grain crops. The Roundup Ready® technology allows corn growers the opportunity to use Roundup Ultra as a tool for managing most annual grass and broadleaf weeds as well as johnsongrass and other perennial species.

Although Roundup Ultra was known to control a wide range of weedy species, there were questions regarding the economics of this technology relative to traditional standard herbicide programs for controlling warm-season annual weeds. The technology fee of $6 per acre for the Roundup Ready® seed was an expense associated with a Roundup weed control program. Furthermore, it was not known if one or two applications of Roundup Ultra would be needed to provide weed control comparable to other products.

The first objective of this research was to compare the effectiveness of Roundup Ready® technology with other herbicide options for managing johnsongrass. A second objective
was to compare the profitability of Roundup Ready® technology with traditional herbicide programs for managing warm-season annual weeds.

Methods
Johnsongrass Control. Experiments were conducted in Princeton and Lexington in 1998 and 1999. Three genetically modified hybrids, each representing a specific herbicide technology, and one non-transformed hybrid were planted at all locations. The hybrids were Garst 8541 IT (for imidazolinone tolerant), Garst 8342 (non-transformed), DeKalb 683 SR (for sethoxydim resistance) and DeKalb 591 RR or DeKalb 626 RR (for glyphosate resistance) in 1998 and 1999, respectively. Plots were 10 feet wide (4 rows) by 30 feet long with four replications. The entire experiment site was treated the day of planting with 4.8 pints of Bicep II to manage weeds other than johnsongrass. Weed control was evaluated visually 2, 4, and 8 weeks after application. The plots were hand harvested by collecting 30 linear feet of row and yields adjusted to 15.5% moisture. Return above fixed and variable costs was calculated by the formula: \[ \text{yield(bu/ac)} \times \$2.06 - [\text{herbicide cost} + \text{fixed and variable cost}] \]. Herbicide costs included cost of the herbicide(s) plus a $6 technology fee for Roundup Ready® treatments and an application charge of $4/ac for each herbicide treatment. A value of $264.54/ac, for variable and fixed costs, was obtained from the University of Kentucky Agriculture Economics Department.

Results and Discussion
Johnsongrass Control. Johnsongrass control ratings four and eight weeks after treatment were variable within treatments and across years. Lightning appeared to be most inconsistent at the four- and eight-week ratings, particularly when its application was made to 8-inch johnsongrass. The level of control observed with Lightning at four and eight weeks after treatment appeared to be better when johnsongrass was 12 inches tall than when plants were 8 inches in height. Inconsistency of control between years was also observed with Accent. Poast Plus and Roundup Ultra provided more consistent control. Only at the eight-week observation date in 1998 did Roundup Ultra or Poast Plus treatments provide less than 90% control. Generally, johnsongrass control in 1998 was less than in 1999 and was attributed to the large rainfall, 20 inches, in June of 1998. Precipitation encouraged further johnsongrass seed germination and emergence and/or regrowth from treated johnsongrass plants.
These data demonstrate that Poast Plus and Roundup Ultra provided superior johnsongrass control compared to Lightning or Accent. Lightning and Accent can deliver acceptable control in any given year, or at any spray timing; however, Roundup Ultra and Poast Plus controlled johnsongrass more consistently.

**Annual Weed Control and Economic Analysis.** Several weeds were evaluated at the various study locations including giant foxtail, common lambsquarters, and giant ragweed. Control of these three species exceeded 90% for all treatments in both 1998 and 1999 (data not shown). In Lexington, the dominant weed species were entireleaf morningglory and common cocklebur. Data are presented for these weed species due to their common occurrence in Kentucky corn production and because they are difficult to control. For entireleaf morningglory and common cocklebur, control ranged between 66 and 100% over both years (Table 2). Sequential Roundup Ultra treatments were highly effective and were not significantly different from the highest control treatment in either year. The chloracetamide + atrazine treatments, not followed by postemergence applications (trts 3, 7, 12), usually had the least control. Treatments consisting of PRE followed by MP combinations consistently were the most efficacious. For all locations and both years, the ASN treatment was required in the form of a single application to 2-4 inch weed regrowth. These data indicate that a single Roundup Ultra application will rarely be sufficient, however a third application will not be required.

Although significant differences in weed control were detected between treatments, no significant differences were observed in yield or return above fixed and variable costs for any treatment (Table 3). These data clearly demonstrate that 100% weed control was not necessary to obtain top yields. It was also readily noticed that a great disparity between yield and net return existed between 1998 and 1999 (Table 3). This was due to the lack of rainfall during the growing season of 1999 that led to low corn yields and negative net return values.

**Summary**

These results demonstrated that Roundup Ultra can be used alone, or sequentially with other products, to deliver effective and consistent weed control over a range of weed species and environmental conditions. There were no differences in return above fixed and variable costs between Roundup Ultra and any of the other herbicide programs compared in this study. Roundup Ready® technology provides another weed management alternative for Kentucky corn growers.

The two years in which these studies were conducted were very different. Growing conditions in 1998 were excellent for corn production resulting in excellent yields in Lexington and Princeton while rainfall was lacking at both locations in 1999 and corn yield was reduced greatly. The extremes in growing conditions provided an opportunity to evaluate Roundup Ready® technology under the “best” and “worst” cases that will be encountered in Kentucky. Consistent weed control was obtained with all herbicide treatments in both years.
