Prevalence

Nearly 70%-90% of individuals in drug treatment programs concurrently use tobacco (Best et al, 1998; Clark et al, 2001)

Kalman, Morissette and George (2005), Am. J. Addict., 14: 106-123
Arguments for Not Providing Tobacco Treatment....

• “these patients don’t want to quit”

• “these patients will relapse if they try to quit”

• “these patients have more important issues in their lives ....they should just be allowed to smoke...”

• “these patients are unable to quit”
Patients Receiving Substance Use and Psychiatric Treatment Want To Quit.....

• Most smokers (80%) in a MMT population were “somewhat” or “very” interested in quitting.

• In an outpatient program for “alcohol abusers”, more than 75% were willing to consider stopping smoking.

• In a review of 9 studies assessing motivation to quit smoking, more than 50% of all smokers with a psychiatric disorder are contemplating to quit smoking in the next 6 months or 30 days.

Richter KP et al. (2001) Tobacco Use and Quit Attempts Amongst Methadone Clients. AJPH
Smoking Cessation Does Not Impair Addiction Treatment But may affect Psychiatric illness ....

• Smoking cessation efforts delivered during addictions treatment appeared to ENHANCE rather than compromise long term sobriety.

• However, smoking cessation is associated with increased risk of depressive episodes among individuals with Major Depression

• May result in adverse drug reaction due to increased available serum levels of antipsychotics (previously lowered by smoking)

These Patients CAN Quit But...

- Earlier meta-analysis (n = 19 studies) addressing smoking cessation among individuals in addiction treatment and recovery found:
  - Increased cessation at end of 12 weeks treatment (BUT NO SIGNIFICANT EFFECT AT 6 MONTHS!)

- Recent study found end-of-treatment smoking cessation rates of 24% vs 19% for individuals with schizophrenia vs. those without psychosis (but with another psychiatric disorder)
  - Longer duration of treatment a significant predictor of successful cessation.

Selby et al. (2010). Individualized smoking cessation treatment in an outpatient setting: Predictors of outcome in a sample with psychiatric and addictions co-morbidity. Addictive Behaviors, 35(9):811-7
Tobacco Dependence Clinic (TDC)
Program Description

Quitting smoking is a process and not an event
Program Description

• Behavioural counselling + 26 weeks of no-cost pharmacotherapy
• Program is run with a team of nurses, counsellors, respiratory therapists, and a physician

• Currently in 7 locations:
  o Pacific Spirit Community Health Centre
  o Raven Song Community Health Centre
  o Three Bridges Community Health Centre
  o Downtown Community Health Centre
  o Pender Community Health Centre
  o Centre for Concurrent Disorders
  o Rainier Hotel
Eligibility:
• 19 years or older
• Tobacco dependent
• Have a history of substance use disorder (SUD) and/or psychiatric disorder (PD)
• Financially disadvantaged

Assessment:
• 1 hour evaluation of medical, psychiatric, substance and tobacco use history
• Expired air CO is determined and a treatment plan is developed in consultation with client
Phases of Treatment

Behavioral Counseling

Support Group

Tailored Pharmacotherapy

8 Weeks

Tailored Pharmacotherapy

Up to 26 Weeks
Behavioral Counseling (Weeks 1-8)

• **Phase 1:** engagement in the process – weeks 1-2

• **Phase 2:** planning for change – weeks 3-4

• **Phase 3:** sustaining change – weeks 5-8
Combination Pharmacotherapy

Nicotine Replacement Therapy
- Patch
- Gum
- Lozenge
- Inhaler

Oral Medications
- Zyban
- Champix
Outcome Evaluation

Smoking Cessation
Specific Aims

• To assess smoking cessation and program completion rates at end-of-treatment

• To examine predictors of smoking cessation
Substance Use Disorder & Psychiatric Disorder History (N = 739)

- Mood: 56.2%
- None: 22.6%
- Anxiety: 14.7%
- Psychotic: 6.5%

Percentages of substance use and psychiatric disorders:
- None: 11.1%
- Alcohol: 35.0%
- Heroin: 10.1%
- Cocaine: 25.8%
- Marijuana: 13.7%
- Metamphetamine: 4.2%

\textsuperscript{a} Employing a two-step model building process in which variables associated with smoking cessation (at alpha < 1.0) in the unadjusted analyses are included in a second-step for adjusted analyses. Only variables which were significantly predictive of smoking cessation in the final adjusted multivariate model are shown.

\* = p < .05, ** = p < .001, *** = p < .001
Summary of Key Findings

• Smoking abstinence at end of program:
  o Intent to treat analysis: 31% (167/540)
  o Among program completers: 41% (167/406)

• Significant predictors of abstinence:
  o Having a history of an anxiety disorder is predictive of being less likely to quit smoking when compared to having no history of a psychiatric disorder.
  o Having a lower CO level at program enrolment was a significant predictor of being more likely to quit
  o Attending the TDC program for a longer duration was a significant predictor of being more likely to quit.
Conclusions

• The Tobacco Dependence Clinic provides an innovative model of tailored tobacco dependence treatment which combines behavioural counselling with no-cost NRT for individuals with a history of substance use and/or psychiatric disorders.

• With intensive tobacco dependence treatment provided within addictions services, individuals with a history of substance use and/or psychiatric disorders are able to achieve smoking abstinence.
The Tobacco-Dependence Clinic: Intensive Tobacco-Dependence Treatment in an Addiction Services Outpatient Setting

3British Columbia Center of Excellence for Women’s Health, Vancouver, British Columbia, Canada

We present outcomes from an intensive tobacco-dependence treatment program for addiction services clients at three different sites. Data from 202 participants were analyzed. For individuals who completed the program, the abstinence rate was 43%. Not having a primary substance use history and a lower carbon monoxide (CO) level at intake predicted abstinence; whereas being female, the particular site of intervention, receiving both nicotine replacement therapy (NRT) and oral medication, and having a lower CO level at baseline predicted program completion. Drug treatment clients can successfully quit smoking at rates similar to the general population when given access to intensive tobacco-dependence treatment. (Am J Addict 2010;00:1-11)

Given that tobacco use remains the number one preventable cause of morbidity and mortality in Canada,7 with alcohol, tobacco, and illicit drug use contributing to 3.1%, 16.5%, and .4%, respectively, of total mortality in Canada8, the high rates of tobacco use among individuals with substance use disorders suggests an increased risk for tobacco-related mortality and morbidity in these populations.

Moreover, several studies have documented the benefits of smoking cessation among individuals with concurrent substance use disorders6,10 such as improved quality of life and drug abstinence12-14. Recent reviews of the li

ABSTRACT

Tobacco use is highly prevalent among individuals with a history of substance use disorders (SUD) and/or mental illness (MI). Despite evidence of differences in smoking cessation (SC) outcomes between women and men, few studies have formally evaluated sex differences among SUD and/or MI populations. For 258 participants (62% male, mean age = 48.6 years) with an SUD and/or MI enrolled in a tobacco dependence clinic (TDC) program, we examined SC outcomes and compared men’s and women’s predictors of end-of-treatment abstinence. Individuals with an MI, social support for quitting, and a greater number of visits to the TDC program were more likely to be female; whereas males were characterized by having an SUD, older age,
