INTRODUCTION

Human sexuality involve sexual attraction to another person, which for the most part is to the opposite sex (heterosexual), some to the same sex (homosexuality), or some having both (bisexuality) or not being attracted to anyone in a sexual manner (asexuality).

Human sexuality is determined by many factors, like cultural, political, legal, and philosophical aspects of life, but also morality, ethics, theology, spirituality, and religion. Sexuality is as old as mankind and interest in sexual activity is very much related to the onset of puberty and the period of schooling.

Primary care physicians see children and adolescents with a wide variety of gynecologic and sexual needs, though they often have limited training and limited available educational materials to help them. We therefore published a small handbook on pediatric and adolescent gynecology with information for the primary care clinician (1), but in this book we have gathered papers from around the world in order to discuss issues of sexuality from an international perspective.

Children and adolescents must successfully traverse various stages of pubertal and sexual development in order to become well-adjusted adults with established sexual identity, functioning, and ability. Concerns with breast development and menstrual function are common issues with adolescent females. The clinician may be presented with children who have pediatric gynecologic complaints (i.e., vulvar bleeding, itching, or a mass) or an adolescent who needs contraception or pregnancy counseling.

In the United States, in 2005 (2), there were 1,225 newly diagnosed cases of HIV/AIDS among adolescents 15–19 years old, and 3,904 among young adults aged 20–24 years (out of 200,000 cases in the United States). There is an estimated one million Americans (4), who are infected with HIV; it is unknown how many are teenagers who will eventually die from HIV in their third or fourth decade of life. Approximately 20% of adults with HIV infection were infected as teenagers and one in four individuals newly diagnosed with HIV infection is under age 22 years. African-Americans are 14% of the American population, yet they bear 28% of the AIDS cases in America. It is estimated that nearly 100,000 women in the United Kingdom develop PID each year. After one episode of STI/STD, 12.8% of young women will suffer from tubal infertility; after three episodes, this figure rises to 75%. However, because most primary care providers do not deal with the complex treatment of AIDS, we will not include a chapter on the subject in this book.

There are approximately three million reported annual cases of abuse in America in those under 18 years of age (5); in 2004 reported cases of maltreatment were subdivided into neglect in 62.4%, physical abuse in 17.5%, sexual abuse in 9.7%, emotional or psychological abuse in 7%, and medical neglect in 2.1% of total cases (1). The epidemiology of rape suggests that, while fewer than one-third of rapes get reported, in three-quarters of cases the perpetrator is known to the woman/victim. The child or adolescent who is subjected to violence and abuse may become an adult with serious sequelae, including diverse mental health disorders. Many cases of physical abuse of
children start out as an attempted sexual abuse and the physical injuries happen as the perpetrator is suppressing the victim’s struggle and resistance.

**CONCLUSION**

The shortage of child and adolescent gynecologists in the world has placed considerable strain on primary care clinicians in helping these children and adolescents, who have a wide variety of sexual and gynecologic needs. The inadequate training primary care clinicians often receive in this area is also worsened by the limited number of available books written for them, which was the reason why we did the pediatric and adolescent gynecology book (1).
