PEPTIDE ELASTASE INHIBITORS AND METHODS

FIELD OF THE INVENTION

This invention relates to inhibitors of the enzyme elastase and more particularly relates to the use of certain novel peptides containing the carbamyl functionality which are active-site directed inhibitors of the enzyme elastase.

BACKGROUND OF THE INVENTION

Proteinases from polymorphonuclear leukocytes and macrophages, especially elastases (human leukocyte elastase and cathepsin G), appear to be responsible for the chronic tissue destruction associated with inflammation, arthritis and emphysema. During infection or inflammation, the normal lung is protected from proteolytic digestion by the protease inhibitor, α1-antitrypsin. The protective mechanism appears to be nonoperative in individuals with an α1-antitrypsin deficiency due to genetic or other causes. Synthetic elastase inhibitors capable of replacing α1-antitrypsin therefore appear to be useful in the treatment of pulmonary emphysema and related diseases.

Although some peptide chloromethyl ketones have been shown to be effective in preventing elastase induced emphysema in animal models "Prevention of Elastase Induced Experimental Emphysema by Oral Administration of a Synthetic Elastase Inhibitor," A. Janoff and R. Dearing, Am. J. Respir. Dis., 121, 1025-3 (1980), there is considerable question whether such reactive agents could be used for treating emphysema in humans. This is not surprising since the alkylation moieties in these inhibitors might render them toxic when used on a continuous basis. To be suitable for human use, an enzyme inhibitor has to show a high degree of selectivity and must have minimal toxic side effects. As a result, most drugs are molecules that reversibly bind to specific enzymes or receptor sites. Examples are the carbamate esters physostigmine and neostigmine which have been clinically used as inhibitors of acetyl choline esterases, A. G. Gilman, L. S. Goodman, and A. Gilman, "The Pharmacological Basis of Therapeutics", p. 101, MacMillan Publishing Co. (1980).

There accordingly remains a need in the art for compounds which are specific and active-site directed inhibitors of the enzyme elastase which are not subject to the disadvantages of compounds known in the art for this purpose.

SUMMARY OF THE INVENTION

It is accordingly one object of the present invention to provide novel compounds which are inhibitors of the enzyme elastase.

A further object of the invention is to provide specific active-site directed inhibitors of the enzyme elastase which are substituted carbamates.

A still further object of the invention is to provide methods for the specific inhibition of porcine pancreatic elastase and human leukocyte elastase by substituted carbamate compounds without affecting the similar serine dependent proteases, bovine pancreatic trypsin and chymotrypsin.

An even further object of the invention is to provide pharmaceutical compositions useful in the specific inhibition of porcine pancreatic elastase, said compositions containing as the active and effective component, certain substituted and novel carbamate compounds.

Further objects and advantages of the present invention will become apparent as the description thereof proceeds.

In satisfaction of the foregoing objects and advantages, the present invention provides substituted carbamate compounds of the following formula:

$$Z-\text{Ala-Ala-Pro-CH}_2-\text{N-C-X-R}$$

wherein Z is selected from the group consisting of R'-O-Suc—where R' is lower alkyl of 1 to 3 carbon atoms, and CF₃CO—, X is oxygen or sulfur, R' is selected from the group consisting of straight or secondary branch-chain alkyl of 2 to 4 carbon atoms, alkynyl of 2 to 4 carbon atoms, alkyl of 1 to 4 carbon atoms, cyclicalkyl of 3 to 6 carbon atoms, preferably cyclopropyl or cyclohexyl, and benzyl, and Z is selected from the group consisting of substituted or unsubstituted phenyl wherein the substituents are selected from the group consisting of nitro, preferably p-nitro, and fluoro, preferably pentafluoro; benzyl, CH₂CF₂CF₂CF₃, 1-lower alkyl-1-phenyl tetrazolyl-, 2-thioxo-3-thiazolinyl, pyridyl, and benzo-
thiazolyl, provided that when R is para-nitrophenyl, R' is other than tertiary-butyl, benzyl, or cyclohexyl, and when X is sulfur, R is other than benzyl.

The invention also provides elastase inhibiting pharmaceutical compositions containing these novel substituted carbamates as the active ingredients, methods for inhibiting the enzyme elastase in animals and humans, and methods for production of the compounds and compositions.

**DESCRIPTION OF PREFERRED EMBODIMENTS**

As pointed out above, the invention relates to certain novel substituted carbamate compounds, pharmaceutical compositions containing these compounds, and methods for use of these pharmaceutical compositions in the specific inhibition of porcine pancreatic elastase and human leukocyte elastase without affecting the similar serine dependent proteases, bovine pancreatic trypsin and chymotrypsin. It is known from the art that proteases from polymorphonuclear leukocytes and macrophages, especially elastases (human leukocyte HL elastase and cathepsin G) appear to be responsible for the chronic tissue destruction associated with inflammation, arthritis and emphysema. During infection or inflammation, the normal lung is protected from proteolytic digestion by the protease inhibitor, α1-antitrypsin. This protective mechanism appears to be non-operative in individuals with an α1-antitrypsin deficiency due to genetic or other causes. Synthetic elastase inhibitors capable of replacing α1-antitrypsin are therefore useful in the treatment of pulmonary emphysema and related diseases.

According to the present invention, a class of compounds containing carbamate functionality and oligopeptides have been found to be active-site directed inhibitors of elastase in animals and humans. This class of compounds therefore provide an opportunity to incorporate chemical moieties which will optimize the affinity of the inhibitor towards the enzyme, and transfer and acylating moiety to the active site of the enzyme. The nature of the acylating moiety could be varied to optimize the duration of enzymatic inactivation.

It is theorized that the mechanism of the invention takes advantage of the fact that the carbamate esters will react with proteases and esterases at the carbonyl carbon by losing the alkoxy portion and transferring the carbamylating moiety to the active site of the enzyme. Decylation will then lead to recovery of enzymatic activity.

The present invention provides a series of carbamate compounds which are active in accordance with the above proposals as elastase inhibitors. These compounds are carbamates substituted by oligopeptides and may generally be described by the following general formula:

\[
\text{Z-Ala-Ala-} \text{Pro-CH}_2-\text{N-} \text{C-X-R} \quad \text{R'}
\]

wherein Z is selected from the group consisting of \( \text{R''O-Suc} \), \( \text{MeO-Suc} \), \( \text{CF}_3\text{CO-Suc} \), and \( \text{MeOSuc} \), \( \text{CF}_3\text{CO} \) ester when \( \text{Z= R''O-Suc} \), e.g., \( \text{MeOSuc} \). These Z-Ala-Ala intermediates may be prepared according to the following scheme:

wherein X is oxygen or sulfur and R is selected from the group consisting of phenyl, fluorophenyl, nitrophenyl, 1-phenyltetrazolyl, 1-lower alkyl tetrazolyl, benzyl, 3-thiazolidinyl, pyridyl, and benzothiazolyl, and R' is straight or secondary branch chained alkyl of 2 to 4 carbons, alkenyl of 2 to 4 carbons, and alkynyl of 2 to 4 carbons, provided that when R is para-nitrophenyl, R' is other than tertiarybutyl, and when X is sulfur, R is other than benzyl; and

wherein Z is selected from the group consisting of MeO-Suc-Ala-Ala and CF3CO-Ala-Ala, wherein R' is as defined above but is preferably isopropyl.

It will be noted from the description of the compounds that the peptidyl carbamates of this invention are those wherein the amino portion contains the oligopeptide and the peptide portion is so chosen as to increase the specificity of the carbamate ester for elastase.

In one embodiment, the compounds of the invention are prepared by a sequential series of reactions beginning with L-proline protected on the ring nitrogen with ultimate coupling to the peptide. In the first step, an N-protected proline, e.g., N-t-BOC-L-proline, is reacted with diazomethane to obtain the diazoketone followed by treatment with HCl to obtain the chloromethyl ketone protected L-proline. The chloromethyl ketone thus obtained is reacted with the appropriate amine \( \text{H}_2\text{NR'} \) to form the protected amine derivative. The amine is in turn reached with the appropriate chloroformate or thiochloroformate and deprotected by reaction with an acid such as HCl to provide the HCl salt. This compound is then coupled with Z-Ala-Ala by the mixed carbonyl anhydride method to provide the compounds of the invention. The Z-Ala-Ala compounds are obtained by reaction of Ala-Ala with methyl succinic acid N-hydroxy succinimide ester when Z=R''O-Suc, e.g., MeOSuc. These Z-Ala-Ala intermediates may be prepared according to the following scheme:
In conducting these reactions, the L-proline in the initial step is protected on the ring nitrogen by reaction with any suitable protective agent known to the art so that reaction will occur on the carboxylic acid portion of the molecule. Preferably, the nitrogen atom in the ring is protected with a known protective agent, such as t-BOC. For example, t-BOC-Pro is available commercially from Sigma Chemical Company, St. Louis, Mo. The protected proline is reacted with diazomethane by the method of Penke et al. (B. Penke, J. Czombos, L. Balaspiri, J. Peters and K. Kovacs, Helv. Chim. Acta., 53, 1057 (1970)). Thereafter, the resulting chloromethyl ketone is then reacted with the appropriate amine. This reaction is preferably conducted in a solvent solution, such as a lower alkyl alcohol, and preferably in the presence of an alkali metal iodide. The reactants are mixed under cool temperatures and then reacted at 50° to 75° C. to complete the reaction. The evolved HCl is neutralized, as with a sodium carbonate solution, and extracted. This intermediate is then reacted with the appropriate chloroformate or thiochloroformate and deprotected with hydrogen chloride to form the carbamate portion of the molecule. This molecule is then coupled with the peptide portion of the molecule to form the final product.

This reaction procedure may be illustrated as follows:

As pointed out above, the compounds of the invention may be employed as specific active site directed inhibitors of the enzyme, elastase. For this purpose, the compounds are preferably combined with a pharmaceutically acceptable carrier for administration by injection or in the oral form. Conventional adjuvants and carriers may be employed in combination with about 0.001 to 2.0 weight percent of the active compound. The compounds may be administered to animals or humans at dosage amounts ranging from about 1 mg/kg up to about 10 mg/kg, preferably an average amount of about 6 mg/kg.

The following examples illustrate preferred embodiments of the invention but the invention is not considered to be limited thereto. In the examples and throughout this specification, parts are by weight unless otherwise indicated.

In synthesis of the compounds of the invention, melting points were determined on a Thomas-Hoover Uni-Melt apparatus and are uncorrected. ’H NMR spectra were obtained using a Varian EM-360 (60 MHz) or EM-390 (90 MHz) spectrometer. Infrared (IR) spectra were recorded on a Perkin-Elmer 567 spectrophotometer. Microanalyses were performed by Atlantic Microlab, Inc., Atlanta, Ga. or by Micro Analysis, Inc., Wilmington, Del. Reactions were routinely followed by thin layer chromatography (TLC) using Whatman MK6F silica gel plates. Spots were detected by UV (254 nm), iodine or HBr-Ninhydrin spraying. Column chromatography was carried out using Silica Gel 60 from E. Merck, Darmstadt, Germany. All compounds were identified by spectral data and elemental analysis.

As pointed out above, the compounds of the invention are useful as elastase inhibitors. To evaluate the compounds, the inhibitory activity of the compounds were tested in vitro against the serine dependent proteolytic enzymes, trypsin, chymotrypsin and porcine pancreatic elastase. All three enzymes belong to the family of serine proteases where the catalytic residues are composed of a triad of amino acid residues, serine, histidine and aspartic acid that actually perform the peptide bond hydrolysis. In addition to the catalytic residues, the active site is composed of an extended substrate binding site that consists of a primary substrate binding site S1, and various subsites on either side of the scissile bond.

The terminology of Schechter and Berger, *Biochem. Biophys. Res. Commun.*, 27, 157 (1980) is used where S1-S2-S1'-S2' refer to subsites on both sides of the catalytic site of the enzyme and the notation P on the substrate (or inhibitor) denotes amino acid residues which bind to these enzyme subsites, such that P1-P1' represents the bond which is cleaved. Substrate specificity studies with HL elastase, Powers et al, *Biochem. Biophys. Acta.*, 485, p. 156, (1977), have shown that substrates with the sequence MeOSuc-Ala-Ala-Pro-Val (representing P3-P2-P3-P2-P1) are highly reactive with the enzyme. The same sequence, although not ideal with PP elastase, was found to react with it effectively. In fact, HL elastase is similar to the more widely studied PP elastase in many respects. They are both serine proteases that show esterase activity toward synthetic substrates such as Boc-Ala-ONp and are both inhibited by α1-anti-trypsin. Furthermore, the natural substrates of these enzymes are very similar.

The results of these evaluations are set forth in the following Tables 1, 2, and 3. The compounds tested as shown in Tables 1, 2, 3, and 4 were prepared as described above.

As will be apparent from the above tables, the useful peptidyl carbamates of the invention were found to exhibit specific inhibition of porcine pancreatic elastase without affecting the other two enzymes. The rate and extent of inhibition could be effected by varying the structure of R and R'. As shown from kinetic parameters when R is p-nitropheno, and R' was varied, all the peptidyl carbamates inhibited PP elastase except when R' was a tert-butyl group. As shown in Table 4, when R' is cyclohexyl and benzy1, the compounds are also inactive. In all cases the inhibition was specific and competitive. When R' was kept as an isopropyl group and R varied, it was found that when R is an aromatic alcohol or thiо-heterocycle with good nucleofugicity, the peptidyl carbamates were specific inhibitors of elastase. However, when R was an aliphatic alcohol or thioalcohol it was found that polyhalogenated groups give better inhibitors than simple hydrocarbons. When compounds where the extended chain was shortened into two amino acids, were tested against the serine proteases, it was found that the inhibitory activity of the carbamates disappeared. Moreover, the nature of the protecting group (P<sub>3</sub>) seemed to affect the affinity of the inhibitor for the enzyme. In all these cases the inhibition was studied at different substrate and inhibitor concentrations and the mode of inhibition determined from Lineweaver-Burk and Dixon plots. Ki values were calculated from the latter. Active peptidyl carbamate inhibitors were found to have a Ki value ranging from 49 μM to 14.8 μM. The Km value for the substrate used (BOC-Ala-ONp) was 4800 μM. The enzymatic activity of PP elastase after treatment with the inhibitor(s) was also tested using the natural substrate elastin-congo red.

In contrast to chloromethyl ketone inhibitors, the carbamate esters of the invention do not inhibit the enzyme permanently as evidenced by the recovery of enzymatic activity of PP elastase in 72 h after inhibition. This reversibility of inhibition, along with the hydrolysis of 6 by PP elastase (as detected by the release of p-nitrophenol) support the mechanism of inhibition proposed herein.

The following abbreviations are used in this specification:  
BOC=t-Butyloxy carbonyl, Ala=L-alanine, Pro=L-proline, Val=L-valine, ONp=p-nitrophenol, PP=porcine pancreatic, HL=human leukocyte. All amino acids used herein are L-amino acids.

From the foregoing description, one skilled in the art can easily ascertain the essential characteristics of this invention, and without departing from the spirit and scope thereof, can make various changes and modifications of the invention to adapt it to various usages and conditions.
