U.S. Department of Transportation

The contents of this report reflect the views of the authors who are responsible for the facts and accuracy of the data presented herein. The contents do not necessarily reflect the official views or policies of the University of Kentucky, the Kentucky Transportation Cabinet, nor the Federal Highway Administration. This report does not constitute a standard, specification, or regulation. The inclusion of manufacturer names and tradenames are for identification purposes and are not to be considered as endorsements.

June 1989
Concern has grown in recent years over the seismic activity of the New Madrid seismic zone in Western Kentucky. Crittenden County, Kentucky is located in this region. To permit emergency medical, supply, and equipment traffic into this area after an earthquake has occurred, the Kentucky Transportation Cabinet is interested in the possibility of keeping selected routes passable. This report lists the routes that have been investigated and recommended as being the routes in Crittenden County that should be maintained in a passable condition. The recommended routes, US 60 and US 641 have been visually surveyed and all seismically significant features cataloged. These features are logged by their location on strip maps contained in Appendix A and a detailed listing of all the potentially critical features is given in Appendix B.
INTRODUCTION

An awareness of earthquakes and their possible effects upon the nation's infrastructure is critically important to the public, and in particular, to public officials. The nation's highway system is one of the most important components of the infrastructure. After the occurrence of an earthquake, the highway system is the primary mode of transporting emergency supplies and services into an affected area. Thus, it is important to catalog the important components of the highway system and attempt to anticipate the possible damage to these components from an earthquake.

Western Kentucky in general and Crittenden County in particular are in a high risk earthquake zone. In 1811-1812, three of the most severe earthquakes in American history shook the country. The location of these quakes was not on the infamous San Andreas fault nor anywhere along the well-known fault laden Pacific coast but was near a small town on the Mississippi River where the states of Kentucky and Missouri share a border (Figure 1). It is this river town, New Madrid, Missouri, that is the namesake of a region now regarded by seismologists and disaster response planners as the most hazardous earthquake zone east of the Rocky Mountains -- the New Madrid seismic zone.

In addition to these three great earthquakes, there are several other well documented factors demonstrating the susceptibility of the New Madrid region to the recurrence of major earthquakes. Through a decade of extensive research, an ancient crustal rift has been found to underlie the relatively shallow sediments comprising the region's surface. This type of geologic structure is prone to seismic activity. The New Madrid rift has been identified as being of sufficient size to generate major earthquakes. Further evidence of the area's seismicity is the record of over 2,000 earthquakes detected in the zone since 1974. Though most have been of a magnitude below the threshold of human perception, their existence clearly indicates the high level of seismic activity occurring in the zone.

Seismologists have calculated the probabilities of recurrence of sizeable earthquakes in the New Madrid rift zone. The probability of a magnitude 6.3 earthquake (Richter scale) within 50 years is from 86 to 97 percent. The probability of that same earthquake occurring within the next 15 years is from 40 to 63 percent. For comparison, the 1971 San Fernando earthquake (magnitude 6.6) killed 58 people and caused $480 million worth of damage. The 1988 Armenian earthquake of similar magnitude killed approximately 25,000 to 30,000 people.

The probability of a magnitude 7.6 earthquake occurring within 50 years is from 19 to 29 percent. The probability for this size earthquake occurring within 15 years drops to a range of 5.4 to 8.7 percent. On February 4, 1975, the Haicheng earthquake in China had a magnitude of 7.3 and destroyed or damaged about 90 percent of the structures in a city of 90,000 people. When comparing historical earthquakes of similar magnitude, one must take into consideration that death totals and damage estimates will vary greatly due to the geology, population density, types of building, and quality of construction.
For a given earthquake, effects at a given location are described by the Modified Mercalli Intensity (MMI) scale (2) which ranges from I (no damage and felt only by instruments) to XII (total destruction). Details of the MMI scale are given in Table 1. Values of MMI associated with the 1811-1812 earthquakes are shown in Figure 1. The potential for damage and destruction from earthquakes in the region is significant.

In 1982, the Governor's Task Force on Earthquake Hazards and Safety was created to evaluate Kentucky's earthquake risk and to make recommendations for responding to those risks. This task force recommended increased public awareness and education programs, improved emergency response planning and training, improved building codes and seismic restraint designs, evaluation of other mitigation measures, and participation in national and regional earthquake forums and funding programs.

In 1984, Governor Collins created the Governor's Earthquake Hazards and Safety Technical Advisory Panel (GEHSTAP) to analyze scientific and engineering data regarding seismic risks in Kentucky and to make specific recommendations on mitigation, public awareness, response planning, and policy development for public health and safety. The States are dependent on their highway systems for the movement of goods and services. Due to the possible adverse effects a major earthquake could have on this system, the Earthquake Stability and Transportation Subcommittee (ESTS) of GEHSTAP was formed.

ESTS has encouraged the Kentucky Transportation Cabinet to secure funding for generating and implementing an earthquake hazard mitigation plan in an attempt to safeguard the highway system against catastrophic earthquake failure. As a result, the Cabinet commissioned the Kentucky Transportation Center at the University of Kentucky to analyze and assess the possible effects of an earthquake on highway facilities. The study area includes the 26 westernmost counties in Kentucky that are adjacent to the New Madrid seismic zone (Figure 1). To date, one of the results of that study has been the recommendation that over 1,000 miles of highways in the study area be utilized as emergency or "priority" routes. These would be the primary routes used for transporting emergency supplies and personnel after an earthquake. Also, it is anticipated that these would be the first routes repaired after an earthquake.

The initial task in identifying these priority routes was to decide where they should begin; that is, in the event of a major earthquake, the point at which the transport of goods and services would originate. Ideally, the city chosen should possess the following attributes:

1. Sufficient size to contain all necessary personnel, supplies, and facilities to respond quickly to a major emergency;

2. Proximity to the high hazard area to speed the relief effort but not so close as to suffer the same high risk potential;

3. Easy access from other major cities in the State; and

4. Sufficient routes to provide relatively direct access to all 26
The city best fitting these criteria is Bowling Green. Located at the eastern edge of the earthquake zone in Warren County, Bowling Green meets both the size criterion (population 40,450) and the accessibility criterion (Louisville and Nashville via I 65 and Lexington via the Bluegrass Parkway). Bowling Green provides access to the 26-county area via US 60/KY 80; this road was chosen as the main east-west artery because it crosses Lake Barkley and Kentucky Lake upstream from the dams impounding those bodies of water.

As a first step towards establishing an overall policy for earthquake hazard mitigation in the highway system, these priority routes have been visually surveyed and all natural and man-made features along these routes that are considered seismically significant were cataloged. With this information, a realistic and cost-effective plan for “hardening” these routes against earthquakes can be established. Such efforts are currently under way.

**PRIORITY ROUTES IN CRITTENDEN COUNTY**

Crittenden County is located approximately 100 miles northeast of the center of the New Madrid Seismic Zone. Figure 1 indicates that Crittenden County is in the IX band of the MMI scale. This indicates considerable damage could occur in Crittenden County in the event of a major earthquake.

US 60 and US 641 have been designated as the priority routes in Crittenden County. US 60 begins at the Livingston County line and continues east 23.00 miles to the Union County line. US 641 begins at the Caldwell County line and continues north 7.40 miles to the city of Marion.

A number of features along these priority routes could potentially hamper rescue and relief efforts. These features included bridges, soil fills, cut slopes, gas pipelines, power lines, power lines, water towers, geologic faults, large trees, mines, water impoundments, and swamps. These features are logged by their location on strip maps contained in Appendix A and a detailed listing of all potentially critical features is given in Appendix B.

**BRIDGES**

Bridges are the most significant and important features on the priority route. With few exceptions, existing highway bridges in the study area have not been designed to resist motions and forces that may be generated by earthquakes. Bridges located within the seismic zone could possibly be damaged, thus reducing their load-carrying ability. In some cases, damage could be sufficiently great to cause complete collapse. Several types of damage could occur:

1. A bridge could fail at the bearing which supports the main spans, causing the spans to fall from the bearings and possibly from the piers or abutments.

2. Failure could occur in the columns, piers, or footings which would reduce the load-carrying capacity of the bridge, if the bridge was still in place.

3. An abutment could tilt allowing the entire span to fall.
4. Soil movement or slumping could affect the bridge approach fills, damaging the abutments or piers, or making the bridge inaccessible.

There are eight bridges on US 60 and one on US 641. The bridges are located at:

**US 60**
1. Crooked Creek,
2. Rush Creek,
3. Winlow Creek,
4. Repton Creek,
5. Mattoon Creek,
6. Hoods Creek,
7. Meadow Creek, and
8. Tradewater River.

**US 641**
1. Crooked Creek,

**FILLS**

Highway fills are particularly important because of their tendency to fail from seismically induced motions. Fills fail in one of two major modes. The first is a generalized circular or wedge-shaped failure resulting in one or both traffic lanes moving down and out. If both lanes failed, this would certainly render the route impassable and immediate repairs would be necessary. The second mode of failure is a general slumping or settling of the embankment. The roadway would probably remain passable if settlement or slumping were not severe but reduced speed limits would be required for safety.

Large fills on the priority routes in Crittenden County are located as follows:

**US 60**
1. 0.60 mile east of the KY 297 (northwest) junction,
2. Approach fills for the Crooked Creek bridge,
3. Approach fills for the Rush Creek bridge,
4. Approach fills for the Winlow Creek bridge,
5. Approach fills for the Repton Creek bridge,
6. Approach fills for the Mattoon Creek bridge,
7. Approach fills for the Hoods Creek bridge,
8. 0.33 mile east of the Hoods Creek bridge,
9. Approach fills for the Meadow Creek bridge,
10. Approach fill for the Tradewater River bridge.

**US 641**
1. Approach fills for the Crooked Creek bridge.

**CUT SLOPE**

Two cut slopes were cataloged during surveys of the priority routes in Crittenden County. Should a cut slope
fail, both lanes of the roadway could be closed. Cut slopes that have a history of failure and those that have steep slopes should be considered as problem areas. Cut slopes are located at:

**US 60**
1. 0.48 mile east of the Hoods Creek bridge.

**US 641**
1. At the Crooked Creek bridge.

**GAS PIPELINES**

Gas pipelines under or near a priority route could fail in the event of an earthquake. If a pipeline failed, an explosion might destroy a section of the priority route. Repair could be delayed by further gas leaks, fire, and/or additional explosions.

It appears that most of the pipelines in Crittenden County were constructed with little or no seismic considerations. One gas pipeline, 0.40 mile north of the Caldwell County line on US 641, was located near a priority route in Crittenden County.

**POWER LINES**

High voltage power lines also were cataloged during the route surveys. The height of the lines above the roadway were estimated visually. Power company officials speculated that a number of breaks along each power line would occur during a major earthquake. In most cases, fallen lines would not be transmitting power because power would be automatically cut off within a few seconds in the event of a break.

In addition to the potential problem of live power lines, power line support towers could fall across and block a priority route. Power lines cross the priority routes at the following locations:

**US 60**
1. 1.00 mile west of the KY 1668 junction, and
2. 1.08 miles east of the Meadow Creek bridge.

**US 641**
1. 0.45 mile north of the Caldwell County line, and
2. 1.31 miles south of the Crooked Creek bridge.

**TOWERS**

There are two towers, 1.82 miles west and 1.08 miles east of the Meadow Creek bridge, on US 60. Structural members or the structure foundation could be damaged during an earthquake and result in closure of the route by a fallen tower.

**TANKS**

There are several storage facilities located near the priority routes in Crittenden County. These facilities could be damaged during an earthquake and block the route. Also some tanks could contain chemicals or fuels that could present additional problems such fire, explosion, or toxic materials. These facilities are located at:

**US 60**
1. 0.59 and 0.54 mile west of the Repton Creek bridge.
GEOLOGIC FAULTS

There are numerous geologic faults (breaks in the bedrock where movement has occurred in the past) in the study area. The faults are seismically significant since a large earthquake could trigger additional movement along one or more old slip planes. There are no precautionary measures that can be taken to reduce hazards from faults except that construction of bridges and other facilities over or near such faults requires special consideration. The faults are included for informational purposes only. Faults which cross under priority routes in Crittenden County are listed below:

US 60
1. 0.95, 3.56, 3.62, 5.21, 5.30, 5.49, and 5.57 miles east of the Livingston County line.

US 641
1. 1.90, 1.77, and 0.08 miles south of the Crooked Creek bridge, and
2. 0.23 and 0.19 mile south of US 60 junction.

MINES

There is a rock quarry 0.28 mile east of the Hoods Creek bridge on US 60. A large earthquake could collapse portions of the quarry walls or collapse underground shafts. Either of these actions could temporarily block or destroy a section of the priority route. Further inspection should be conducted to determine if this mine constitutes a probable threat to the priority route.

TREES

The behavior of trees during an earthquake depends upon many factors including their condition, type, height, and size. Local soil conditions, geometry of the ground surface, and characteristics of the earthquake can also be important. Violent ground motions accompanied by surface rupture and perhaps permanent displacement of the soil surface produce sudden surface accelerations of the ground which can snap and uproot large trees. Trees are so numerous that, if many of them fell, the priority routes could effectively be blocked for several hours or days before emergency crews could clear the debris. Groups of large trees are located near the road at the following sites:

US 60
1. 0.20 mile east of the KY 91 junction,
2. 0.15 mile west and 0.80 mile east of the Winlow Creek bridge,
3. 0.04 mile west of the Repton Creek bridge,
4. 0.17 mile west of the Hoods Creek bridge, and
5. 1.72, 1.42, 1.09, and 0.30 miles west and 0.43 and 1.08 miles east of the Meadow Creek bridge.
1. 0.55 and 3.20 miles north of the Caldwell County line,
2. 1.66 and 0.26 miles south of the Crooked Creek bridge, and
3. 0.64, 1.34, and 1.74 miles east of the Crooked Creek bridge.

**ALLUVIUM**

Soil maps for Crittenden County indicate that there are large amounts of alluvium present throughout the county. Alluvium is a loose, fine-grain soil which is deposited by flowing water such as creeks and rivers. Due to the nature of the alluvium, ground motions at the surface of the soil can be many times greater than those within the underlying bedrock and temporary liquefaction can occur (Figure 2). An alluvium map for Crittenden County is shown in Figure 3.

**CONCLUSIONS**

In 1984, ESTS developed a fivefold plan of action for formulating and implementing a seismic mitigation policy for the western Kentucky seismic zone. To date, the Kentucky Transportation Center has established priority routes for all 26 counties in the western Kentucky seismic zone and developed seismic risk maps of all natural and man-made features that are susceptible to earthquake damage that could jeopardize the priority routes.

Current work is being conducted to analyze these features and make recommendations for hardening them against earthquake damage.

Future work involves training key personnel in the Transportation Cabinet in hazard mitigation and seismic safety, which includes bridge inspectors, district engineers, construction inspectors, designers, and maintenance personnel.

Following the education of key personnel, the mitigation plan proposed by the Kentucky Transportation Center will be reviewed by the Kentucky Transportation Cabinet and a program will be established for implementation. The final step involves the use of relevant seismic codes for all new construction, repair, and maintenance.

Additional Information

The Commonwealth of Kentucky has prepared a State Emergency Operations Procedures (State EOP) manual that is produced by the Division of Disaster and Emergency Services (DES), Department of Military Affairs, Frankfort, 40601. Annexes H. on Transportation and DD on Earthquakes give additional information on disaster preparedness and response.

A copy of the State EOP and information on local hazard mitigation activities and response preparedness are available from the AREA 2 Office of DES which is located in Hopkinsville. The phone numbers at this office are (502) 564-8602 and (502) 885-7100.

Additional information about the study discussed in this report should be directed to David L. Allen, Project Director, at the Kentucky Transportation Center, (606) 257-4513. Requests to be placed on the mailing list for updated information should be submitted on your company or agency letterhead to the Kentucky Transportation Center at the University of Kentucky, Lexington Kentucky 40506-0043.

## Table 1: MODIFIED MERCALLI INTENSITY SCALE

<table>
<thead>
<tr>
<th>Version</th>
<th>Modified Mercalli Intensity Scale, 1956</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The following comments by Dr. Richter precede the published statement of the intensity scale:</td>
</tr>
<tr>
<td></td>
<td>Each effect is named at the level of intensity at which it first appears frequently and characteristically. Each effect may be found less strongly, or in fewer instances, at the next lower grade of intensity; more strongly or more often at the next higher grade. A few effects are named at two successive levels to indicate a more gradual increase.</td>
</tr>
<tr>
<td></td>
<td>Masonry A, B, C, D. To avoid ambiguity of language, the quality of masonry, brick or otherwise, is specified by the following lettering.</td>
</tr>
<tr>
<td></td>
<td>Masonry A. Good workmanship, mortar, and design; reinforced, especially laterally, and bound together by using steel, concrete, etc.; designed to resist lateral forces.</td>
</tr>
<tr>
<td></td>
<td>Masonry B. Good workmanship and mortar, reinforced by not designed in detail to resist lateral forces.</td>
</tr>
<tr>
<td></td>
<td>Masonry C. Ordinary workmanship and mortar; no extreme weakness like failing to tie corners, but neither reinforced nor designed against horizontal forces.</td>
</tr>
<tr>
<td></td>
<td>Masonry D. Weak materials, such as adobe; poor mortar; low standards of workmanship, weak horizontally.</td>
</tr>
<tr>
<td></td>
<td>The following list represents the twelve grades of the scale.</td>
</tr>
<tr>
<td></td>
<td>I. Not felt. Marginal and long-period effects of large earthquakes.</td>
</tr>
<tr>
<td></td>
<td>II. Felt by persons at rest, on upper floors, or favorable placed.</td>
</tr>
<tr>
<td></td>
<td>V. Felt outdoors; direction estimated. Sleepers awakened. Liquids disturbed, some spilled. Small unstable objects displaced or upset. Doors swing, close, open. Shutters, pictures move. Pendulum clocks stop, start, change rate.</td>
</tr>
<tr>
<td></td>
<td>VII. Difficult to stand. Noticed by drivers of motor cars. Hanging objects quiver. Furniture broken. Damage to masonry D, including cracks. Weak chimneys broken at roof line. Fall of plaster, some bricks, stones, tiles, ornaments. Some cracks in masonry C. Waves on ponds; water turbid with mud. Small slides and caving in along sand or gravel banks. Large bells ring. Concrete irrigation ditches damaged.</td>
</tr>
<tr>
<td></td>
<td>VIII. Steering of motor cars affected. Damage to masonry C; partial collapse. Some damage to masonry B; none to masonry A. Fall of stucco and some masonry walls. Tearing, pull of chimneys, hayracks, monuments, towers, elevated tanks. Frame houses moved on foundation if not bolted down; loose panel walls thrown out. Damage to water tanks. Trees broken from roots. Changes in flow or temperature of springs and wells. Cracks in wet ground and on steep slopes.</td>
</tr>
<tr>
<td></td>
<td>IX. General panic. Masonry D destroyed; masonry C heavily damaged, sometimes with complete collapse; masonry B seriously damaged. Frame structures, if not bolted, shifted, or foundations. Frame cracked; frame damage to reservoirs. Underground pipes broken. Conspicuous cracks in ground. In alluviated areas sand and mud ejected, earthquake fountains, sand crater.</td>
</tr>
<tr>
<td></td>
<td>X. Most masonry and frame structures destroyed with their foundations. Some well-built wooden structures and bridges destroyed. Serious damage to dams, dikes, embankments. Large sand slides. Water thrown on banks of canals, river, lakes, etc. Sand and mud shifted horizontally on beaches and flat lands. Rails bent slightly.</td>
</tr>
<tr>
<td></td>
<td>XI. Rails bent greatly. Underground pipelines completely out of service.</td>
</tr>
<tr>
<td></td>
<td>XII. Damage nearly total. Large rock masses displaced. Lines of sight and level distorted. Objects thrown in the air.</td>
</tr>
